

## ARTICLE XV.

Report of the Committee on the Solar Eclipse of May 14 and 15, 1836. Read July 19, 1839.

The committee on Astronomical Observations, to whom were referred several communications relative to the Solar Eclipse of May 14 and 15,1836 , respectfully report:

That the American observations, as far as received, on whose accuracy sufficient reliance may be placed, are the following, and are given in mean time of the places of observation.

| No. | Observer. | Place of Observation. | Latitude. | Longitude W. of Green wich. | Plase. | Mean Time of Ob servation. |

The correction of the chronometers, at Philadelphia, was determined by a twenty inch Jones's transit instrument, with high and low stars. The corrections of the deviations of the instrument were computed, and applied. Eastern and western altitudes of the sun were measured by two observers, with different sextants.

This eclipse was more extensively observed in this country than any of the preceding eclipses. Its principal phases had been announced for a great number of places, by a member of this committee, Robert Treat Paine, Esq., in the American Almanac for 1836. Equations for the times of the principal phases, (on the method of Woolhouse,) for places near Philadelphia, by another member of the committee, Mr Sears C. Walker, had been published in the April number of the Journal of the Franklin Institute. Preliminary computations and formulæ for its principal phases for European observatories had appeared in the Berliner Jahrbuch, and more particularly in the Nautical Almanac, by Mr Woolhouse. The central and annular path of this eclipse traversed England and Germany. The weather in the United States was unusually fine. In England and Germany the fairness of the weather was such, that few disappointments were experienced by observers situated in its annular path. It was however rainy in Bohemia and Bavaria. In Prussia, Poland and Austria,
the weather was generally fine. Northward of Germany the weather was unfavourable. In consequence of the extent of the civilized nations traversed by this eclipse, and of the atmospheric circumstances favourable in the main, it is believed to have furnished a greater number of observations, for geographical and physical purposes, than any other eclipse on record, not excepting the memorable total eclipse of September 7, 1820. The number of spots on the sun's dise was unusually great. The position of these spots, relative to the sun's centre, was carefully determined by Dr Peters, from Schumacher's observations at Altona, on the morning and afternoon of the 15th, with a twelve inch Ertel's equatorial. The times of their contact with, and total obscuration by the moon's limb, were extensively observed, and are placed on record. It does not however appear that any important consequences have yet been derived from this kind of observations. The details of the circumstances of this eclipse are given in full in the $13 t h$ and 14 h volumes of Schumacher's Astronomische Nachrichten, and in the 10th volume of the Memoirs of the Royal Astronomical Society of London. Among the papers on this subject, the committee would mention, with particular approbation, that of Bessel, No. 320 Astr. Nachr.; of Rumker, No. 319; and of Dr Peters, No. 326 ; as also Bailey's paper, in the Memoirs of the Royal Astronomical Society, vol. 10, a copy of which (the gift of the author) is placed in the archives of this Society. A reprint of a part of Bailey's paper was exceedingly useful in directing the attention of observers to the remarkable phenomena of the annular eclipse of September 18, 1838. In anticipation of a more full report on the eclipse of 1838 , the committee would here remark the fortunate circumstance of the attention of observers being thus directed to these singular appearances; and that the presence in the same building of telescopes of equal optical capacity, furnished with screen glasses of different colours, and their use by the same observer interchangeably, have shown that these remarkable appearances may be modified, if not wholly changed, by the nature of the medium through which they are beheld. The committee indulge a hope that this subject will receive particular attention in future central eclipses, and that the records of the past will be searched into, by those who are possessed of the means, in order to show how far the discrepancies of former observations may be explained by the effect of the screen glass
used. In the paper of Professor Bessel, above referred to, are given the analytical formulæ, perhaps the most perfect yet furnished, for the reduction of observations of a solar eclipse for geographical purposes. In Dr Peters's paper, Bessel's method has been applied to the European observations of this eclipse; below will be given the result of an application of the same to the American observations, by Mr Walker. The committee notice, with pleasure, the adoption of these formulæ, in making announcements of solar eclipses, in the Berliner Jahrbuch for 1840 , by which nearly one half the labour of an isolated computation will be saved. The committee have also to acknowledge, on behalf of the Society, the receipt, through the attentions of Mr A. D. Bache, of a valuable paper on the solar eclipse of the 3 d and 4th of March 1840, by Mr C. Rumker, director of the Hamburg observatory. This present was accompanied with a circular, requesting a communication of the American observations of the solar eclipse of May 14, 1836, of which the European ones had been already reduced by that distinguished astronomer, and published in No. 319 of the Astr. Nachr.

A copy of the American observations was furnished to Mr Rumker, through Mr John Vaughan, by a member of this committee. In return for this, the Society has received from Mr Rumker the paper read at their last meeting, which the committee recommend for publication among the documents connected with this eclipse.

It would have been highly acceptable to the committee, had Mr Rumker resolved the equations of condition, which he has obtained, in order to afford to the Society all the advantages which this eclipse is capable of furnishing, for geographical purposes. In the absence of such a result, the committee have appended the computations of Mr Walker, in which the longitudes derived from Rumker's eqnations of condition are compared with those formerly obtained by Mr Walker, from the same observations, reduced by Bessel's method, using chiefly Peters's co-ordinates and corrections of the tabular elements. The circumstance noticed by Mr Rumker, that the coefficients of the corrections of the moon's latitude and parallax, are affected with opposite signs in the European and American observations, is one of great importance, inasmuch as it facilitates the determination of the latter, and thus affords a rare comparison with the results of meridian
altitudes of the moon in northern, contrasted with those made in southern parallels of terrestrial latitude. The value of $d \varpi$, or the correction of Burckhardt's constant of parallax, as found by Mr Walker, is $+1^{\prime \prime} 516$. Burckhardt's constant is $57^{\prime} 0^{\prime \prime} \cdot 5$, making, when this correction is applied, $57^{1} 2^{\prime \prime} \cdot 0$. It appears from Mr Henderson's memoir on the Constant Quantity of the Moon's Equatorial Horizontal Parallax, (see Memoins of the Royal Astronomical Society, vol. $10, \mathrm{p} .294$, ) in which he has discussed an extensive series of meridian observations of 1832 and 1833, with mural circles, at Greenwich, Cambridge and the Cape of Good Hope, that the value of this constant is $57^{\prime} 1^{\prime \prime} \cdot 8$.

It is seldom that solar eclipses have been accurately observed over a portion of the earth's surface large enough to admit of the coefficient of parallax thus changing its sign; occultations of planets and stars of the first magnitude can hardly be expected to furnish equations of condition capable of determining the constant of the moon's parallax with precision. The difficulty of locating observers at convenient places for this purpose, and the uncertainty concerning the precise instant of an immersion or emersion at the moon's bright limb, must continue to furnish obstacles nearly insuperable. The importance, therefore, of Mr Rumker's paper is much enhanced by the rare opportunity which it affords. For the purpose of comparison, the principal values of the moon's horizontal equatorial parallax, yet obtained, are here collected together. They are found chiefly in Mr Henderson's Memoir. They are as follows:

[^0]$57^{\prime} 2^{\prime \prime} \cdot 64$ Olufsen, from the same, using compression $\frac{1}{302 \cdot 02}$.
$57^{\prime \prime} 2^{\prime \prime} \cdot \% 6$ Henderson, from the same, using compression $\frac{1}{300}$.
$57^{\prime} 1^{\prime \prime} .80$ Henderson, as above mentioned, from meridian observations at the Cape and at Greenwich and Cambridge, in 1832 and 1833. This result depends upon an assumed compression, $\frac{1}{300}$, and gives the moon's mass $\frac{1}{78 \cdot 9}$, and the coefficient of lunar nutation $9^{\prime \prime} \cdot 28$.
$57^{\prime} 0^{\prime \prime} .43$ De Ferrer, from fifteen occultations with meridian observations, and six corresponding occultations.
$5 \%^{\prime} 2^{\prime \prime} .00$ S. C. Walker, from Rumker's computations of the eclipse of May 14 and 15 , 1836, compression $\frac{1}{302 \cdot 78}$.

$\left.\begin{array}{l}\text { R. M. PATTERSON, } \\ \text { S. C. WALKER, } \\ \text { R. T. PAINE, } \\ \text { ANDREW TALCOTT, }\end{array}\right\}$ Committee.
Letter of Mr Charles Rumker to Mr John Vaughan, Librarian of the American Philosophical Society at Philadelphia.

Observatory, Hamburg, March 27, 1839.
Sir:
I have to apologize for the delay of the calculation of the valuable American obsèrvations of the Solar Eclipse of May 15, 1836, and have now the pleasure of sending you them, together with those of a number of European ones, that have partly been communicated to me since. On account of the opposite parallaxes and latitudes of the moon, her elements might, by a comparison of the American observations with the European ones, be correctly determined. I have used in the calculation, moon's latitude at mean noon at Greenwich, $=$ $19^{\prime} 43^{\prime \prime} 1 \%$, N ., ©'s sem. $=14^{\prime} 50^{\circ} 4, \odot^{\circ}$ 's semidiameter $=15^{\prime} 48^{\circ} 4$, which is founded partly upon a comparison of all the observations, partly upon actual measurement of breadth of the $\odot$ 's illuminated dise at the time of the greatest obscuration, and finally, upon a comparison of the calculation at places situate upon the borders of the annulus, with the observations made there.

Your most obedient servant,
CHARLES RUMKER.
P.S. The calculations of the true ecliptic conjunction, as well as of the coefficients of the corrections of semidiameters, ©'s lat. and par. have been carefully revised, so that I believe this collection of observations to be useful for determining the errors of the lunar elements. Particularly, I think that the annular observations, where the signs of the moon's apparent latitude change, deserve some attention.

The weather was not favourable, at Hamburg, for observing the solar eclipse of March 15, 1839, but at Rostock, in latitude $54^{\circ} 5^{\prime} 45^{\prime \prime} \mathrm{N}$. and longitude $39^{\circ} 20^{\prime}$ east of Paris, it was observed by Professor Karsten.

## Poland.

## Spain.

Note by the Committec.-The latitudes and longitudes of the American places of observation, reported by the committee, are the result of the most recent determinations, and differ, in some instances, from those furnished at an earlier date to Mr Rumker.

## Letter of Mr Sears C. Walker.

Philadelphia, July 10, 1839.
To the Committee on Astronomical Observations.

## Gentlemen:

Being desirous of deducing the longitudes of the American places of observation from Rumker's expressions for the mean time of conjunction, I have formed thirty-eight equations of condition, from the duration of the eclipse, by subtracting the expression of the conjunc-tion-time derived from the end from that furnished by the beginning, and in a similar manner have obtained seven equations from the observed duration of the ring. Of the last I reject that which is derived from No. 44. I thus find by

$$
\begin{aligned}
& \text { No. (12)-No. (14); } \quad 0=-1^{\prime / .08} \underbrace{\Delta(\odot-D)} \underbrace{\Delta \beta}_{-0.0504} \underbrace{\Delta \pi}_{-1.3730} \underbrace{\Delta \pi}_{-0.3630} \\
& \text { No. (41)-No. (18); } \quad 0=-3.65-0.5063-0.8249+0.5336 \\
& \text { No. (33)-No. (35); } \quad 0=+7.60+0.6563-1.8772+0.3036
\end{aligned}
$$

whence,
(a)

$$
\Delta \beta=0.7044+0.0492 \times \Delta(\odot-D)+0.1163 \times \Delta \pi
$$

Substituting this value in the seven equations of condition from the duration of the ring, we have from

No. (12); $\Delta(\odot-D)^{(0)}=+0^{\prime \prime} .030+0.0606 \times \Delta \pi$
No. (14); $\Delta(\odot-D)^{(r)}=-0.429-0.0569 \times \Delta \pi$
No. (33); $\Delta(\odot-D)^{(11)}=-0.501+0.0812 \times \Delta \pi$
No. (18); $\Delta(\odot-D)^{(\text {III })}=+0.814+0.2966 \times \Delta \pi$
No. (35); $\Delta(\odot-D)^{(1 \mathrm{v})}=+0.869-0.0718 \times \Delta \pi$
No. (41); $\Delta(\odot-D)^{(\mathrm{v})}=+1 \cdot 626+0.2490 \times \Delta \pi$
No. (44); $\Delta(\odot-D)^{(\mathrm{rl})}=-3 \cdot 161+0.0644 \times \Delta \pi$

Rejecting Nos. (41) and (44), which differ most from the mean, and taking the mean of the remaining numbers, there results,
(b)

$$
\begin{aligned}
\Delta(\odot-D) & =+0^{\prime \prime} .1566+0.0619 \times \Delta \pi \\
\Delta \beta & =+0.7121+0.1193 \times \Delta \pi
\end{aligned}
$$

The sum of the equations Nos. (1) to (11), inclusive, rejecting Nos. (16) and (10) from the United States observations, give (c), and the equations from the European observations, rejecting Nos. (17), (18), (20) and (45) give (d), as follows :
(c) $. .0=50^{\prime \prime} \cdot 86+43 \cdot 6745 \times \Delta(\odot+D)+14 \cdot 2733 \times \Delta \beta-5 \cdot 1156 \times \Delta \pi$
$(d) .00=113 \cdot 19+101 \cdot 1848 \times \Delta(\odot+D)-5 \cdot 1929 \times \Delta \beta+13 \cdot 7391 \times \Delta \pi$
Equations (b), (c) and (d), give,

$$
\begin{aligned}
& \Delta(\odot+D)^{(\mathrm{r})}=-1^{\dot{4}} 3972+0.0781 \times \Delta \pi \\
& \Delta(\odot+D)^{(\mathrm{u})}=-1.0823-0.1297 \times \Delta \pi
\end{aligned}
$$

and,

$$
\begin{aligned}
\Delta(\odot+D) & =-1^{11} \cdot 279 \\
\Delta(\odot-D) & =+0 \cdot 250 \\
\Delta \beta & =+0.893 \\
\Delta \pi & =+1.510
\end{aligned}
$$

But according to Rumker's letter,

$$
\begin{aligned}
\Delta^{\prime}(\odot+D) & =-1^{\prime \prime} \cdot 000 \\
\Delta^{\prime}(\odot-D) & =-2 \cdot 000 \\
\Delta^{\prime} B & =-7 \cdot 630 \\
\Delta^{\prime} \pi & =0 \cdot 000
\end{aligned}
$$

whence, denoting by $d$ the sum of the corrections respectively denoted by $\Delta$ and $\Delta^{\prime}$, we have,

$$
\begin{aligned}
d(\odot+D) & =-2^{\prime \cdot} \cdot 279 \\
d(\odot-D) & =-1 \cdot 750 \\
d \beta & =-6 \cdot 736 \\
d \pi & =+1 \cdot 516
\end{aligned}
$$

VI. -4 X
which are the most plausible values of the corrections of the tabular elements that I am able to deduce from Rumker's expressions for the conjunction-times. I have given the method of solution somewhat at length, in order that every one may judge whether other modes of combining together the equations of condition might not give more probable results.

With these corrections, and using the longitudes of observatories as given in Rumker's letter, the Greenwich mean time of conjunction is as follows:

This conjunction-time gives the following longitudes from Greenwich, of the American places of observation; to which I have also appended the results which I have already published in the Journal of the Franklin Institute for August 1838, and which are obtained by using Bessel's method, with Peters's co-ordinates for the end, and mine for the beginning of the eclipse. The corrections of the tabular elements being those obtained by Dr Peters, viz., $\varepsilon=-3 \cdot{ }^{\prime \prime} 650$, $\xi=-5 \cdot{ }^{\prime \prime} 472, \quad n=0$.

|  | tred | ced. |  | 45 | $38 \cdot 33$ |
|  |  | , |  |  | $16 \cdot 92$ |

Robert Treat Paine, Esq. has informed me that he has found the longitude of Brown University, Providence, $4 h 45 m 42 \cdot " 03$, and that of Dorchester, $4 h 44 m 20^{\prime \prime} \cdot 45$, from the observations of this eclipse, at these two places and at Greenwich. In making the computations he has used, $\quad d \lambda=-3^{\prime \prime} \cdot 60, d \beta=-7^{\prime \prime} \cdot 63, d(\odot+D)=-1^{n} \cdot 87$. The longitude of Providence from Boston is the same by both computations.

The mean time of the ecliptic conjunction, by the N. Almanac, is $2 h 7 m 0^{\prime \prime} \cdot 3$; by observations as above, $2 h 7 m 5 \cdot 25 s$; whence, $d \lambda=-2 \mu .276$.

The corrections, $d \lambda, d \beta$ and $\boldsymbol{d} \boldsymbol{\pi}$, from Rumker's equations, may readily be referred to the moon's orbit, and its secondaries, by means of formulæ derived from Airy's Table of Factors (Greenwich observations, 1836), and from Bessel's 'Theory of Equations, as follows:

$$
\begin{gathered}
\Delta \alpha=15 \cdot \frac{\mathrm{~S} \Delta \lambda+\mathrm{Q} \Delta \beta}{\mathrm{PS}-\mathrm{Q} \mathrm{R}} \\
\Delta \delta=\quad \frac{\mathrm{R} \Delta \lambda+\mathrm{P} \Delta \beta}{\mathrm{PS}-\mathrm{QR}} \\
\Delta \delta=\sin \mathrm{N} \cos \delta \Delta \alpha+\cos \mathrm{N} \Delta \delta \\
\varepsilon=-\cos N \cos \delta \Delta \alpha+\sin \mathrm{N} \Delta \delta-\pi \cos \pi \Delta \pi \\
\zeta=-1
\end{gathered}
$$

Where, from Peters's co-ordinates for $3 h \mathrm{~m}$. t., Berlin, and Airy's factors, we have,

$$
\begin{aligned}
& x=+0.47147=\mathrm{L} \sin 1^{\prime \prime} \operatorname{cosec}_{\pi} . \\
& \mathrm{L}=\text { least distance of centres on true orbit in seconds of arc. } \\
& \mathrm{N}=70^{\circ} 11^{\prime} 10^{\prime \prime} \cdot 4=\text { moon's orbital angle. } \\
& \alpha=521348^{\prime \prime} \cdot 2=\text { moon's true right ascension. } \\
& \delta=+192240^{\prime \prime} \cdot \mathbf{~}=\text { moon's true declination. } \\
& \pi=\quad 5424^{\prime \prime} 1 \quad=\text { moon's horizontal equatorial parallax. } \\
& \mathrm{P}=+\quad 13^{\prime \prime \cdot} \cdot 720 \\
& \mathrm{Q}=-\quad 0^{\prime \prime \cdot} \cdot 244 \\
& \mathrm{R}=+\quad 3^{\prime \prime} \cdot 470 \\
& \mathrm{~S}=+\quad 0^{\prime \prime} \cdot 969
\end{aligned}
$$

Whence there results the following comparison:

$$
\begin{aligned}
\underbrace{\text { From Rumker. }} & \underbrace{\text { From Peters. }} \\
\varepsilon=-2^{\prime \prime} \cdot 934, & \varepsilon=-3^{\prime \prime} \cdot 650 \\
\zeta=-7 \cdot 198, & \zeta=-5 \cdot 472-0 \cdot 159 \times \eta^{\prime} \\
& =-5 \cdot 750
\end{aligned}
$$

In which $\varepsilon$ is the correction of the moon's tabular place on its orbit, and $\zeta$ on a secondary to its orbit.

Respectfully,
SEARS C. WALKER.
